

File permissions in Linux

Project description

[Describe what you accomplish through Linux commands.] I examined and changed file and directory permissions in Linux. I used Linux commands to identify incorrect permissions and then used `chmod` to remove unauthorized access. The goal was to make sure only the correct users and groups had access to the files and directories.

Check file and directory details

I navigated to the projects directory using : `cd projects`. I used : `ls -l` to display the files, tier permissions, owners and groups. I also used : `ls -ls` to display hidden files along with their permissions. The files were owned by researcher2, and the group associated with the files was `research_team`.

Describe the permissions string

Linux permissions are shown as a 10- character string, such as: `-rw-----`. The first character was the file type. A `-` means its regular file, while `d` means is directory. The remaining characters were divided into three groups: owner, group, and other.

Change file permissions

I found files that had permissions that were not authorized and changed them using `chmod`. For example ; `chmod g-rw project_m.txt` . I removed read and write permissions from the group.

Change file permissions on a hidden file

I used `ls -la` to find `.project_x.txt`, then change it so the user and group could only read it.
`Chmod ug=r .project_x.txt`

Change directory permissions

I checked the drafts directory with: `ls -ld drafts` . Then I removed group execute permission: `chmod g-x drafts`. This made sure only the owner had access.

Summary

I used ls commands to check permissions and chmod to change read, write, and execute access for files and directories.
